

The Post Storage Version accepts all the incoming mail, store a copy redundant and then forward it to the current mail system. This is realized without any current post servers configuration and without any post client configuration adjustment. These Post Storage Systems get fed by an extra set of domain name dns records.

The Post Storage Versions has of course standard triple internal redundancy, but here also can be chosen for extra or local/building and/or global/geographical redundancy.

The Post Redundancy Version filters (spam/viruses) and then stores and forwards all incoming mail (storing outgoing mail is also an option).

Each mail is stored as a separate file on the file system. This is why the Post Storage Version is as fast as the file system. All files are indexed once and there is a special index to each email attached index file created.
